

# **Collaborative Programming**

**Working as a Solo Developer**

**Working in a Small Team ( 2-5 )**

**Working on a Open Source Project**

# What does Industry wants ?

## Dream

Coding, testing, marketing and communications skills a must. Do you have what it takes to be a dream developer in 2016?

**Polyglot**  
The multilingual programmer is going to have his or her pick of jobs, and a lot of company—88% of developers report that they're skilled in more than one language.

**0101**  
**New to coding?**  
Welcome! You can still be hired. Today, 30% of developers have less than five years of experience.

**Customer friendly**  
Ready, willing and able to meet with customers? You're hired.

**Education**  
High school diploma and an app dev boot camp certificate? You're hired. Community college diploma? You're in. Self-taught? You're probably hired, too. Four-year university degree? You'll have a job also—but too bad about those student loans.

**Business skills**  
If you can use a spreadsheet, write a business plan or stay within a budget, your résumé will be at the top of the pile.

**Location independent**  
Software development jobs are everywhere, so if you're not picky about location, you'll have plenty of options. If you are choosy, you may be able to work remotely.

**Special skills**  
Cloud, mobile, UX, of course, or perhaps you really enjoy maintenance coding or have a secret love of COBOL. No matter, these skills are a fast track to employment.

**Industry background**  
Marketing, healthcare, manufacturing or knowledge of a specialized industry + software coding = command your own salary.

## Developer

## Cowboy

## Developer

# Who is a Cowboy Coder ?

A programmer with little regards to best practices

# Martin Flower

**Good Programmer write code that humans understand**

# A Typical Scenario

A client has asked you (**Developer**) to make a Website

He has requested a new feature few days back but on

intermediate delivery to remove it

But after few days he has requested again for the same

feature in the final delivery of the website

# A Typical Scenario

## Challenge 1

How will the developer find the code for the last implemented feature

## Solution 1

Developer has to search all his emails with the client conversation

## Challenge 2

Project has multiple file changes to achieve the feature

## Solution 2

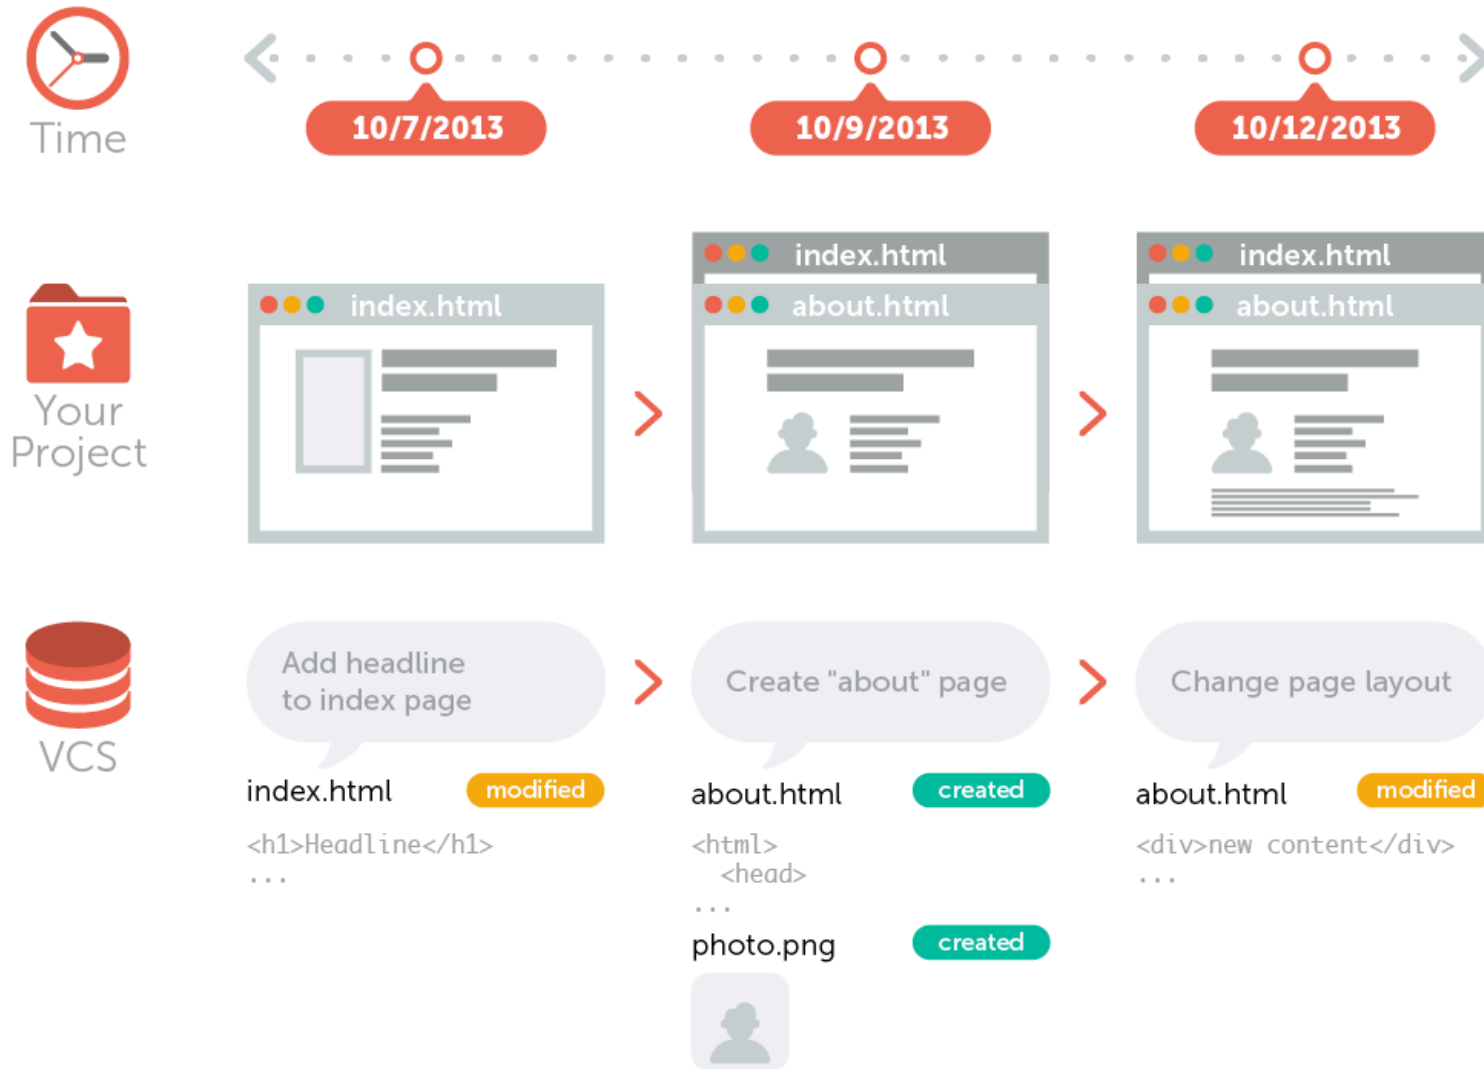

Keep the backup of full project by zipping it with time stamps

# Best solution is a System to ...

- keep track of changes to files
- let you undo mistakes
- work on different versions of same project

# What is Version Control System (VCS) ?

# Why use VCS or SCM ?

Enforce Discipline

Archive Versions

Maintain Historical Information

Enable Collaboration

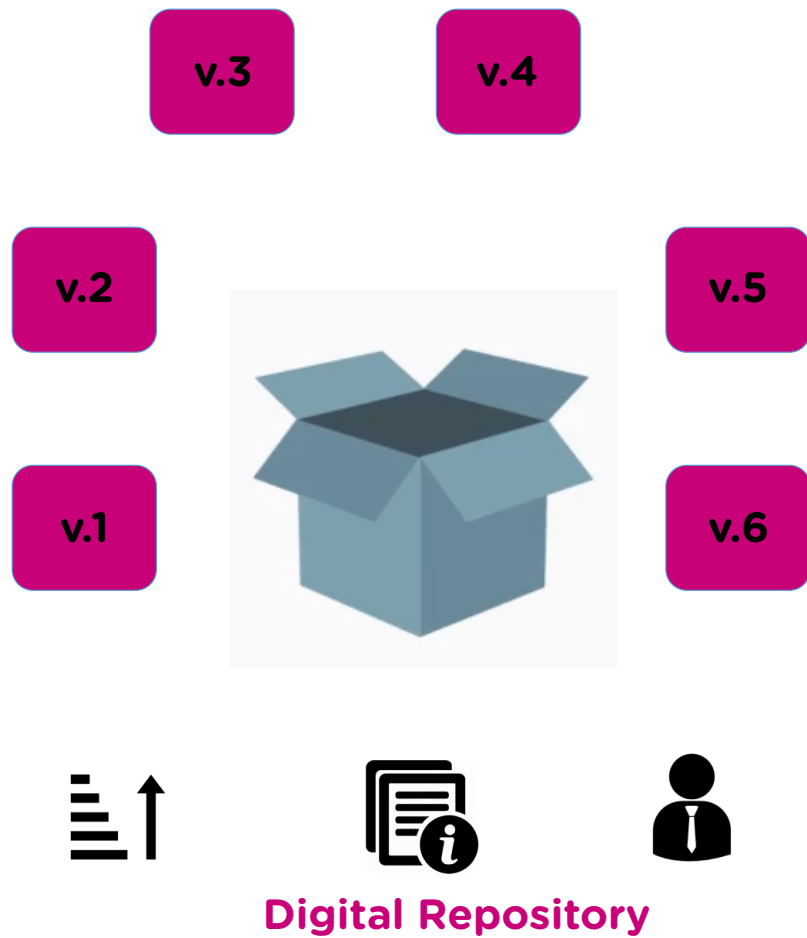

Recover from accidental deletions or edits

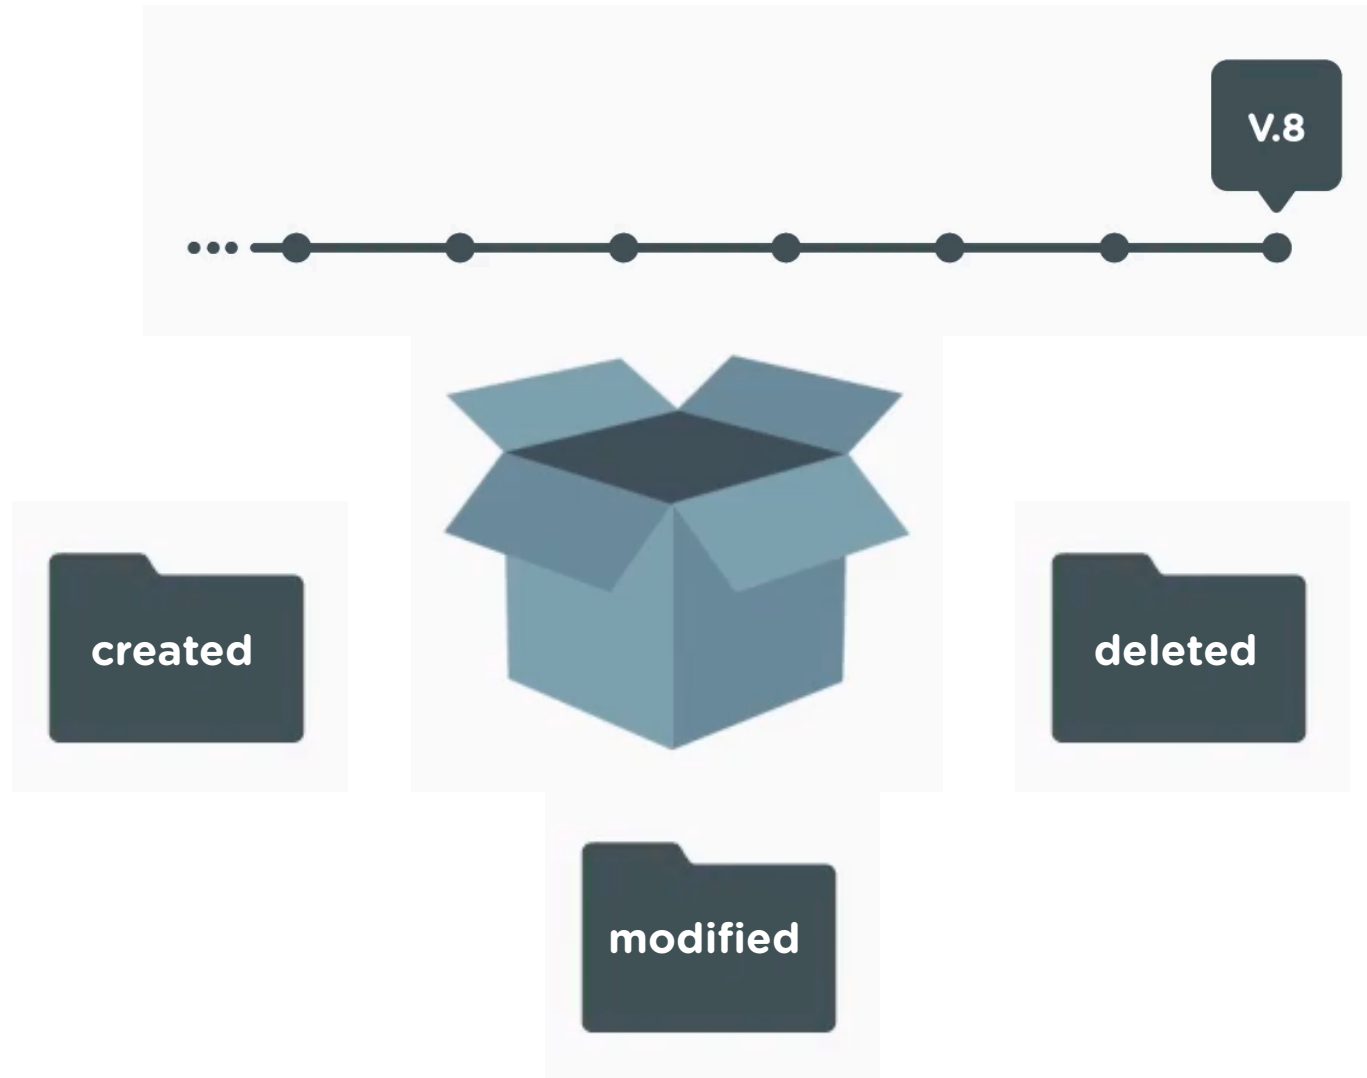

Conserve Disk space

\*SCM = Source Code Management

# How VCS looks like?

# How VCS works ?

# Which VCS to use ?

**Centralized**

**SVN**

**Mercurial**

**De- Centralized**

**Perforce**

**GIT**

# Quiz

Which of the following does git do ?

- **keep track of changes to files.**
- **Notice conflicts between changes made by different people.**
- **Synchronise files between different computers.**
- **All of the above.**

# Answer

Which of the following does git do ?

- ☐ keep track of changes to files.
- ☐ Notice conflicts between changes made by different people.
- ☐ Synchronise files between different computers.
- ☒ All of the above.

# How to verify that **git** is installed ?

## ■ mac ( on terminal )

```
$ git --version  
git version 2.6.4
```

## ■ linux ( on terminal )

```
$ git --version  
git version 2.6.4
```

## ■ windows ( on git bash )

```
$ git --version  
git version 2.6.4
```

# Setting up **git** on your computer ?

## ■ **mac**

It's installed with Xcode

or:

<http://git-scm.com/download/mac>

<http://code.google.com/p/git-osx-installer>

## ■ **linux**

\$ **sudo yum install git**

or:

\$ **sudo apt-get install git**

## ■ **windows**

<http://msysgit.github.io/>

or:

<http://git-scm.com/download/win>

# How to re-verify that **git** is installed ?

## ■ mac ( on terminal )

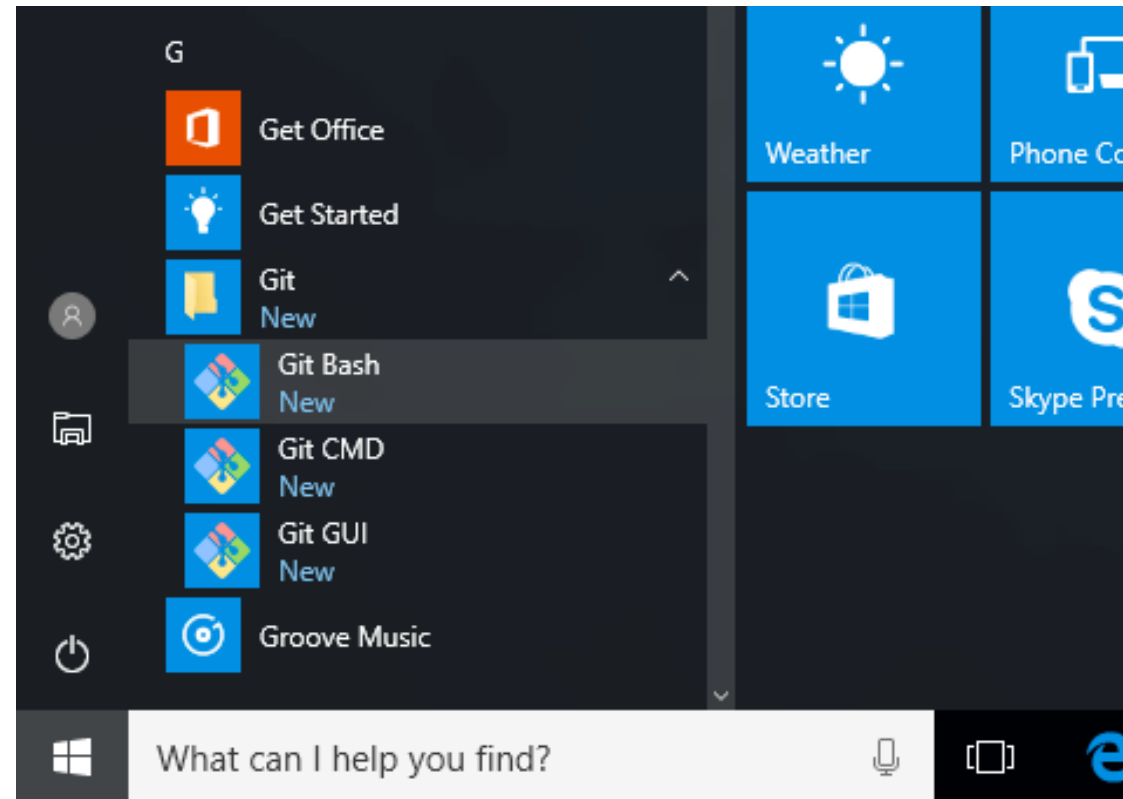

```
$ git --version  
git version 2.6.4
```

## ■ linux ( on terminal )

```
$ git --version  
git version 2.6.4
```

## ■ windows ( on git bash )

```
$ git --version  
git version 2.6.4
```

# How can I see **git** is configured ?

```
$ git config --list
```

```
$ git config --global user.name
```

```
$ git config --global user.email
```

```
$ git config --global color.ui
```

# How can I change my **git** configuration ?

```
$ git config --global user.name "Dr. Sylvester Fernandes"
```

```
$ git config --global user.email "sylvester@forsk.in"
```

```
$ git config --global color.ui true
```

# What is a Working Directory?

A folder containing the files you want to track

The folder of your project

# What is a Local Repository or repo ?

Think of a **repo** as a kind of database where your VCS stores all the versions and metadata

**repo** is just a simple hidden folder named “.git” in the root of the working directory

# Create a Empty Repository of working dir

```
$ cd ~/Documents
```

```
$ git init my_repo
```

{ Initialized empty Git repository in /Users/sylvester/Documents/my\_repo/.git/ }

Or

```
$ cd ~/Documents
```

```
$ cd old_proj
```

```
$ git init
```

{ Initialized empty Git repository in /Users/sylvester/Documents/old\_proj/.git/ }

# Empty Repository created

# Delete a Repository of a working dir

```
$ rm -r my_repo/.git
```

All git information is stored in a .git folder in the project's root.

Just delete the .git folder, the history is gone

# Repository deleted

my\_repo

# Quiz

Suppose your home directory `/home/repl` contains a repo `dental`, which has a sub directory `data`. Where is the information about the history of the files in `/home/repl/dental/data` stored ?

- ☐ `/home/repl/.git`
- ☐ `/home/repl/dental/.git`
- ☐ `/home/repl/dental/data/.git`
- ☐ None of the above.

# Answer

Suppose your home directory `/home/repl` contains a repo `dental`, which has a sub directory `data`. Where is the information about the history of the files in `/home/repl/dental/data` stored ?

- ☐ `/home/repl/.git`
- ☒ `/home/repl/dental/.git`
- ☐ `/home/repl/dental/data/.git`
- ☐ None of the above.

**commit ( snapshot / taking a picture )**

**commit is a snapshot of your project at a certain point of time**

**keep track of your changes by committing changed files to the repo**

use the **"\$git status"** command to get a list of all the changes you performed since the last commit

# Golden rule of VCS !!

**No. 1: Git doesn't tracks files by default**

**No. 2: Commit early, commit often**

**No. 3: Commit Only Related Changes**

**No. 4: Write Good Commit Messages**

# Status of file in repo

- **untracked** – new file that's never been added to vcs
- **tracked** – new file that's been added for tracking
  - **working** – Tracked files with new changes
  - **staged** – File added to staging area
  - **committed** – File is added to local repo

# Getting an Overview of Your Changes?

```
$ git status
```

untracked

staged

new file

modified

committed

# How can I view repo history ?

```
$ git log
```

# Whats the first steps in saving the change 🧙

```
$ touch README.txt
```

```
( $ git status )
```

```
$ git add README.txt
```

```
( $ git status )
```

# How do I commit changes ?

```
$ git commit -m "My first commit"
```

"\$git log" command lists all the commits that were saved in chrono order

"\$git status" command to get list of all changes to local repo

```
$ mkdir my_repo && cd my_repo
```

(Empty dir)

my\_repo

# \$ git init

Workspace

addition

# How can I view a specific file history ?

```
$ git log path/to/file
```

# How can I view a specific commit ?

```
$ git show few/char/of/hash
```

# How can I see what changed between 2 commits ?

```
$ git diff ID1..ID2
```

**hands-on for first  
commit**

# Your second commit

```
$ notepad README.txt
```

```
$ git add .
```

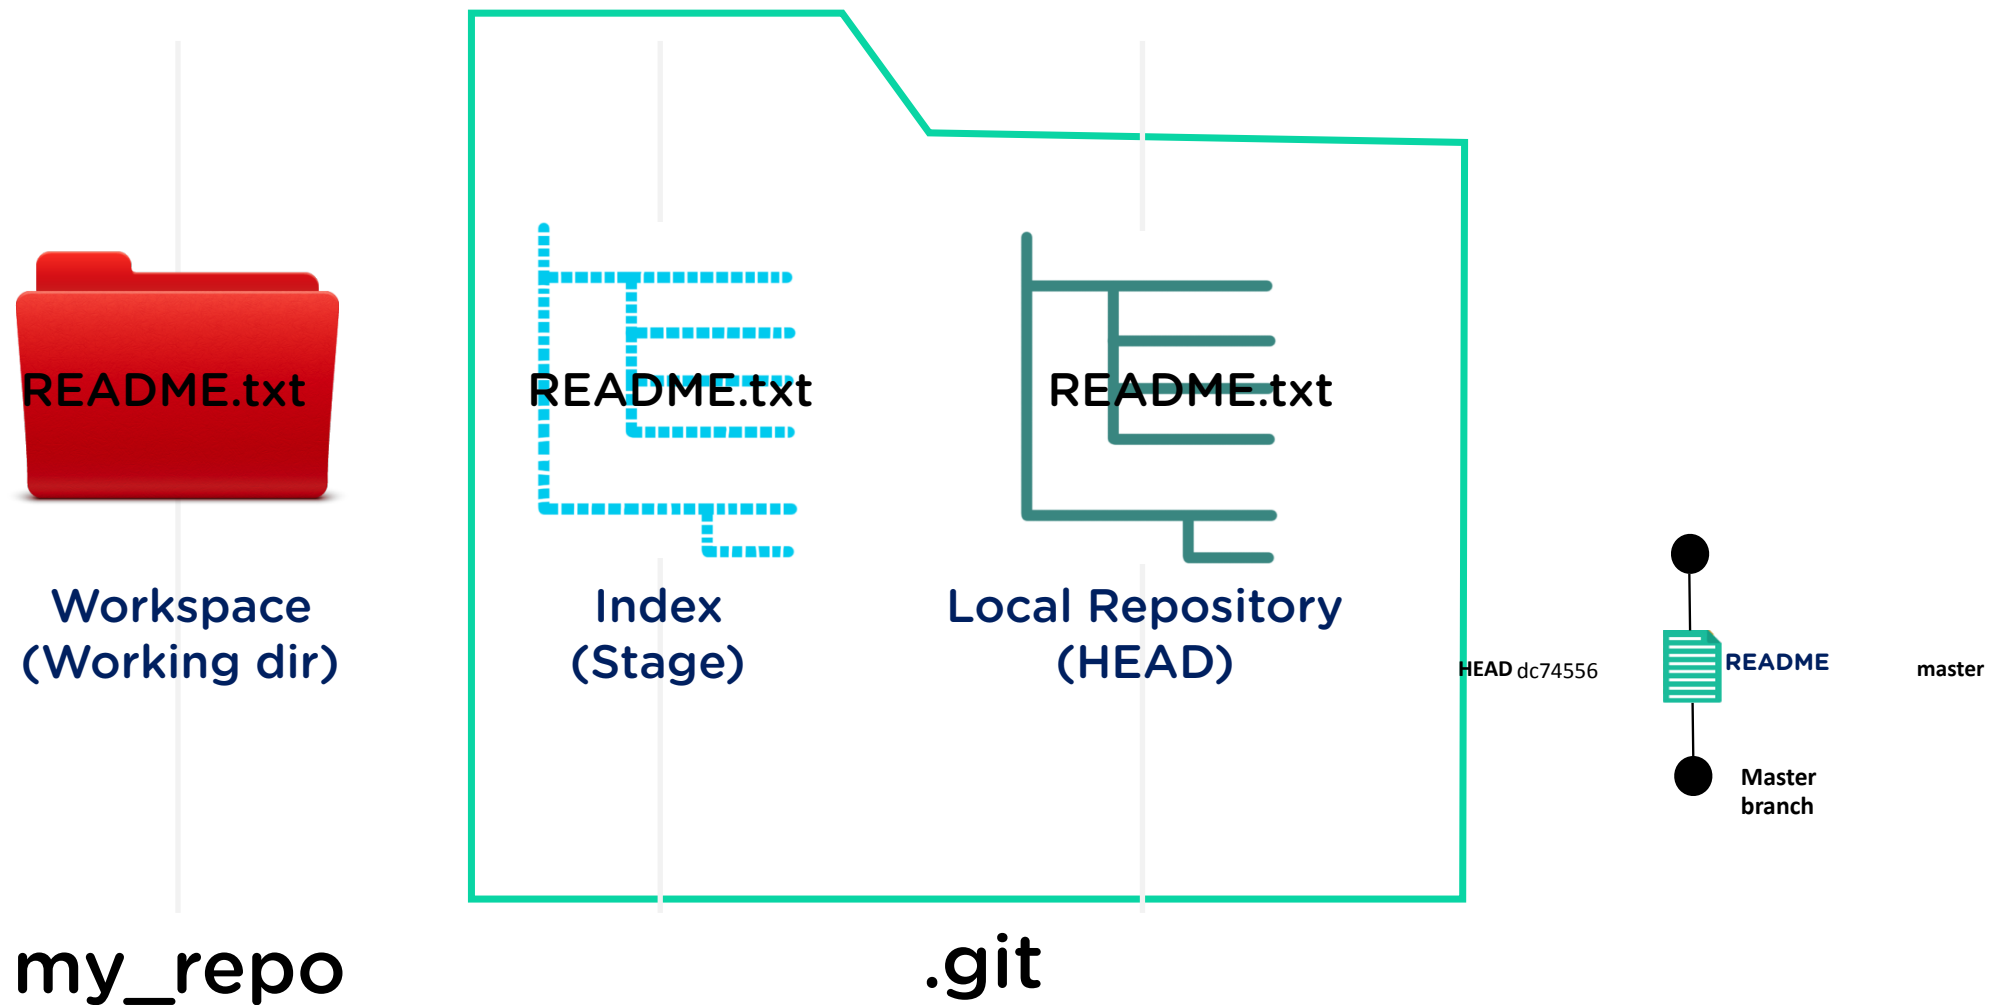

```
$ git commit -m "My sec commit"
```

Or

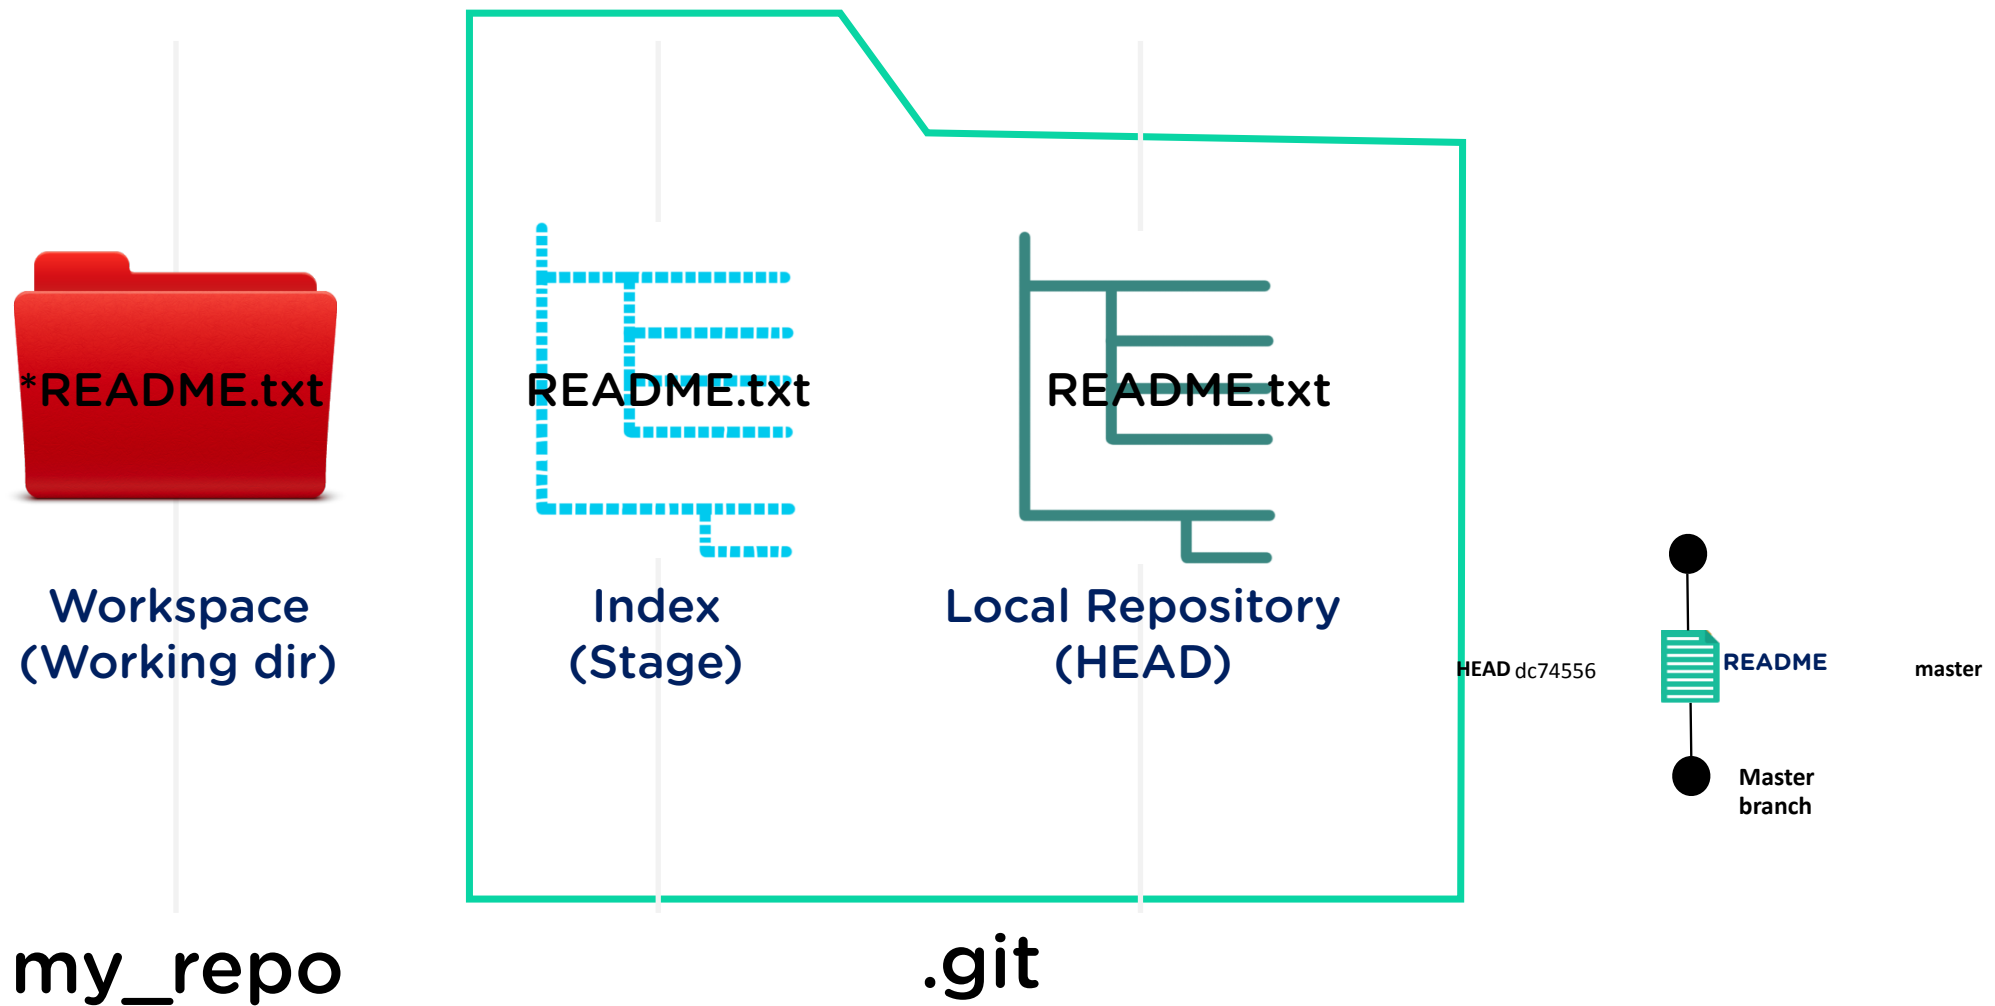

```
$ git commit -a -m "My sec commit"
```

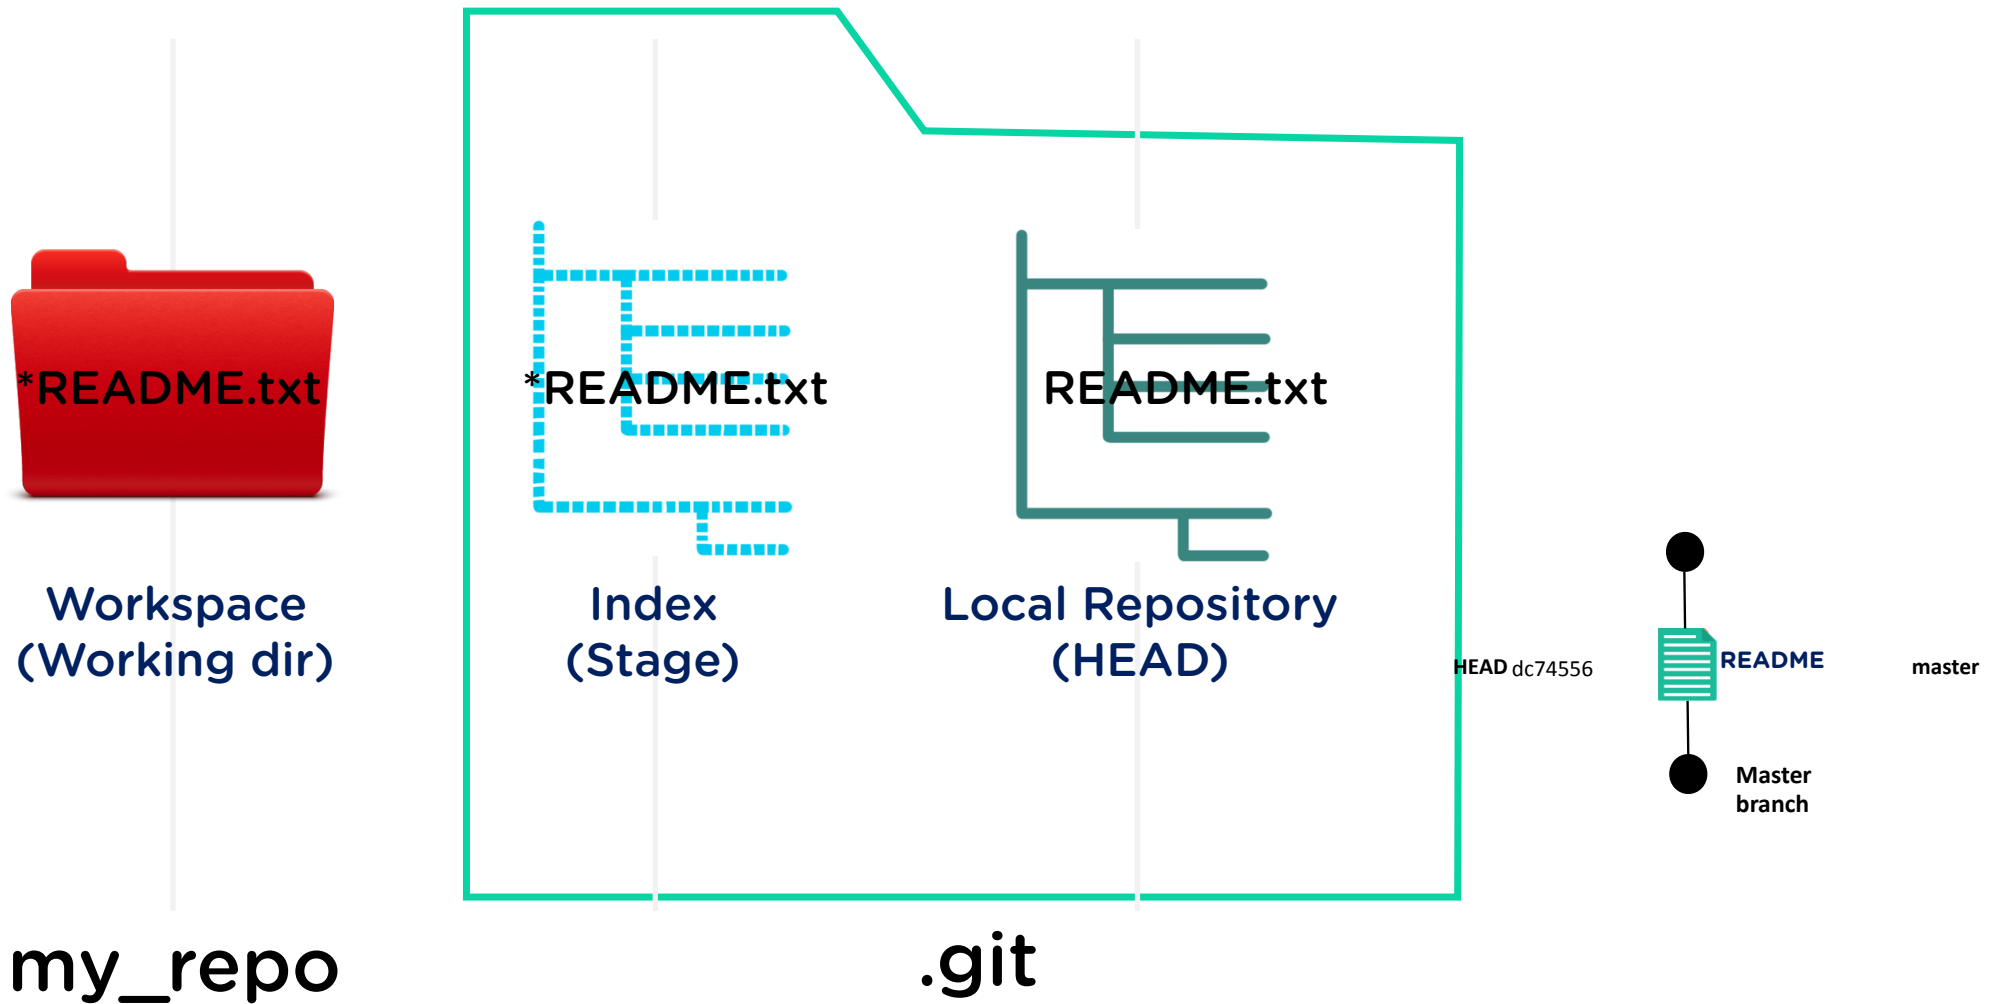

# What's happening in Directory ?

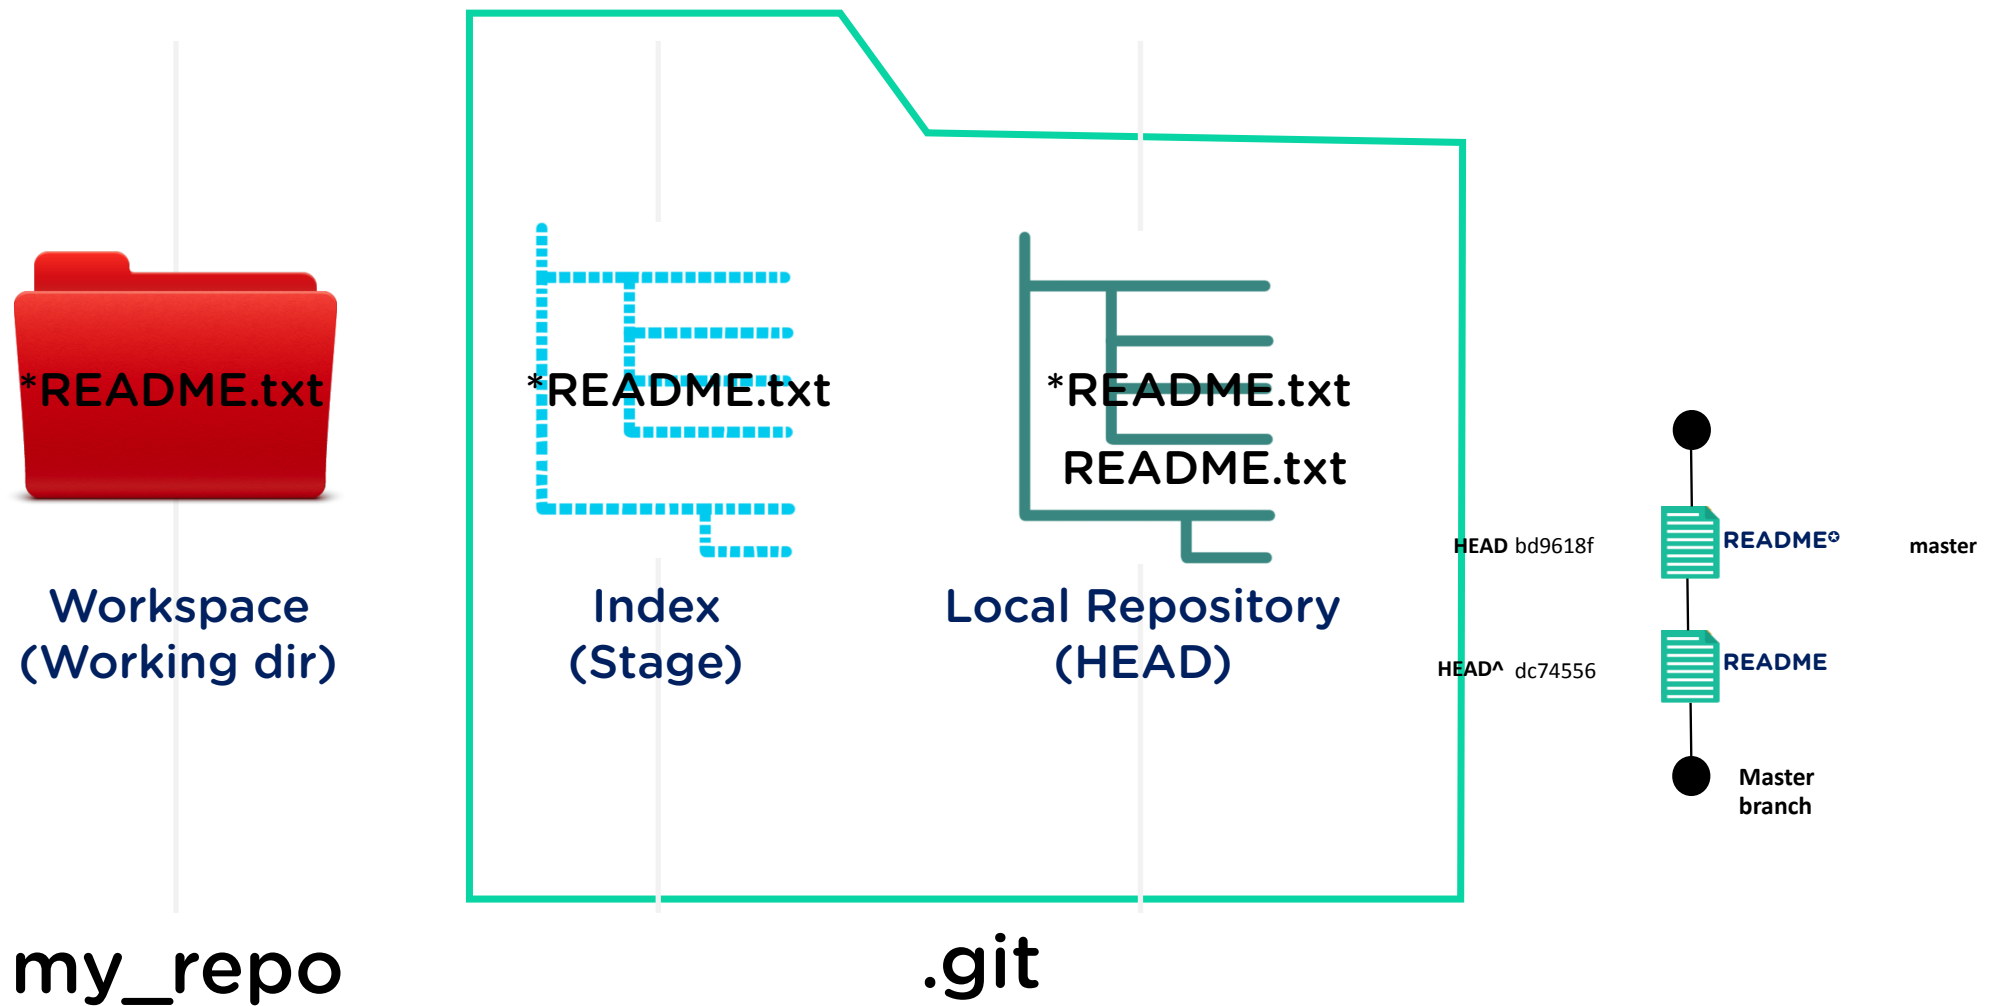

# \$ notepad README.txt

\$ git add .

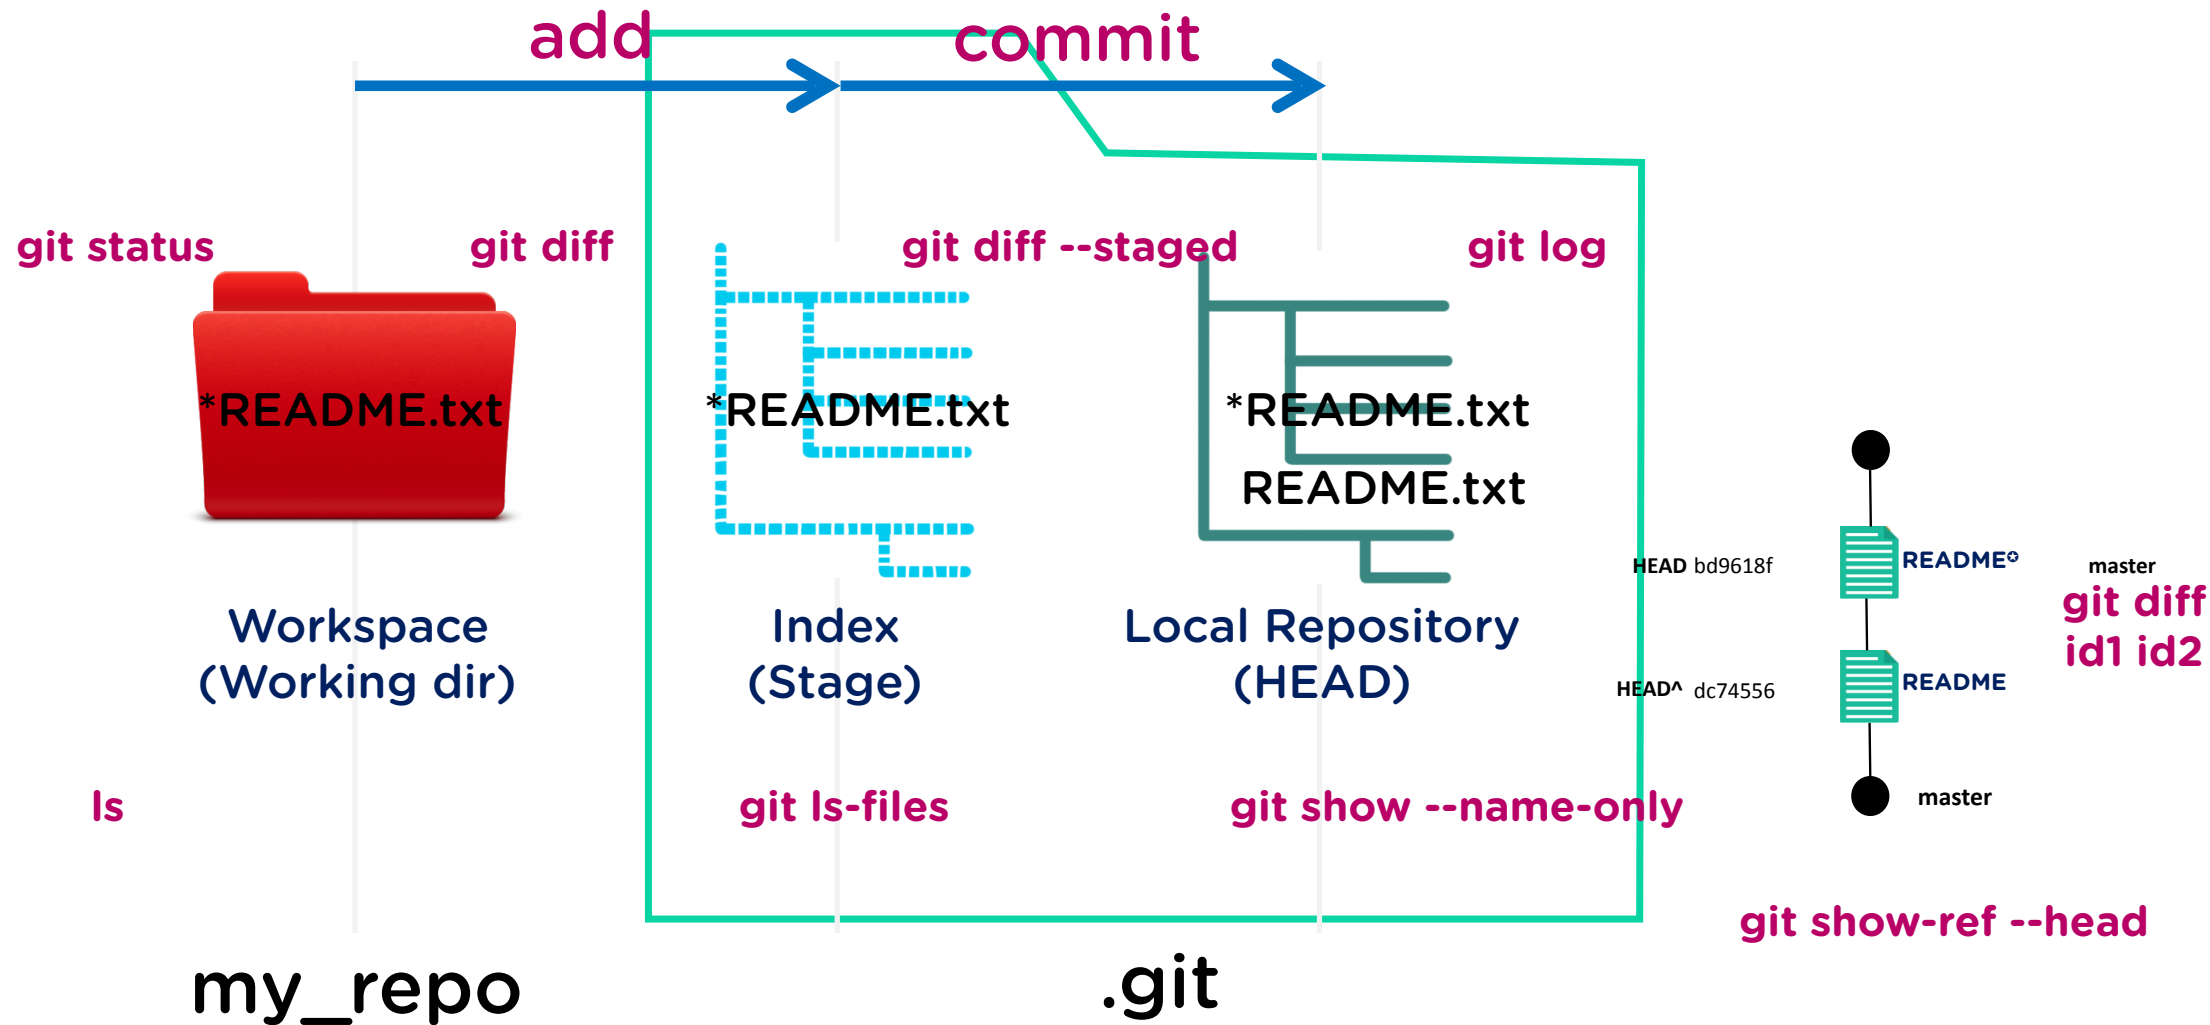

# \$ git commit -m "Second commit"

# hands-on for second commit

# Summary of commands

# When things go wrong

# Messed working but NOT staged

```
$ git checkout HEAD path/to/file
```

Revert to the last committed version of the file  
( If file is NOT committed and NOT staged )

This brings from the repo to the staging area and working directory

# Messed working (but staged)

```
$ git reset HEAD path/to/file
```

Brings the file from repo to the staging area  
and also Un-stage the staged file, it resets the file to the state you last staged.

and then

```
$ git checkout HEAD path/to/file
```

This brings the file from staging area to the working directory  
this is undoing the changes

# Messed working (staged and commit)

\$ **git checkout HEAD^** path/to/file

Revert to version of file from prior to latest commit  
( HEAD^ represents the prior to latest commit )

Careful: this overwrites changes to files in your working area and staging area  
HEAD~1 can also be used

the act of restoring the file is saved as another commit, because you might later want to undo your undoing.

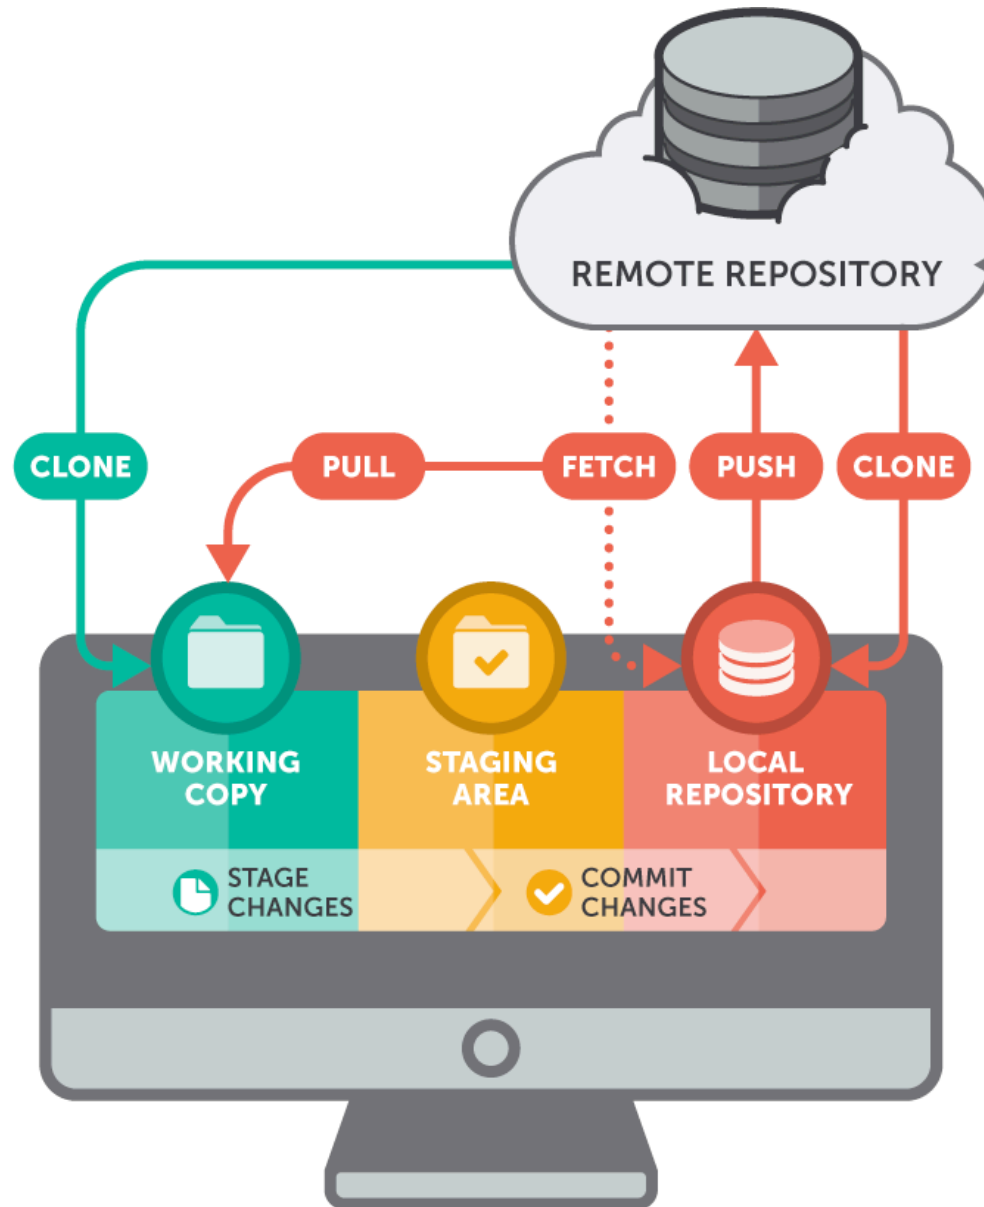

**My Laptop got  
crashed/stolen**

**Solution !!**

Working with  
Remote Repo  
on cloud to backup and  
share with other  
developers

# Github / Bitbucket

- **Create** an account on Github
- **Update** profile
- **Explore** Github
- Create a new public **empty repo**
- **Push** your local repo to remote repo
- **Open** the link in browser to view files

# Adding remote to local repo

```
$ git remote -v
```

To show your remotes for repo

```
$ git remote show origin
```

to show your remote named origin

```
$ git remote add name/of/remote https/path/to/repo
```

you can connect to many remotes as you like

```
$ git remote add origin https://github.com/neuerung/my_repo.git
```

# Pushing local repo to remote

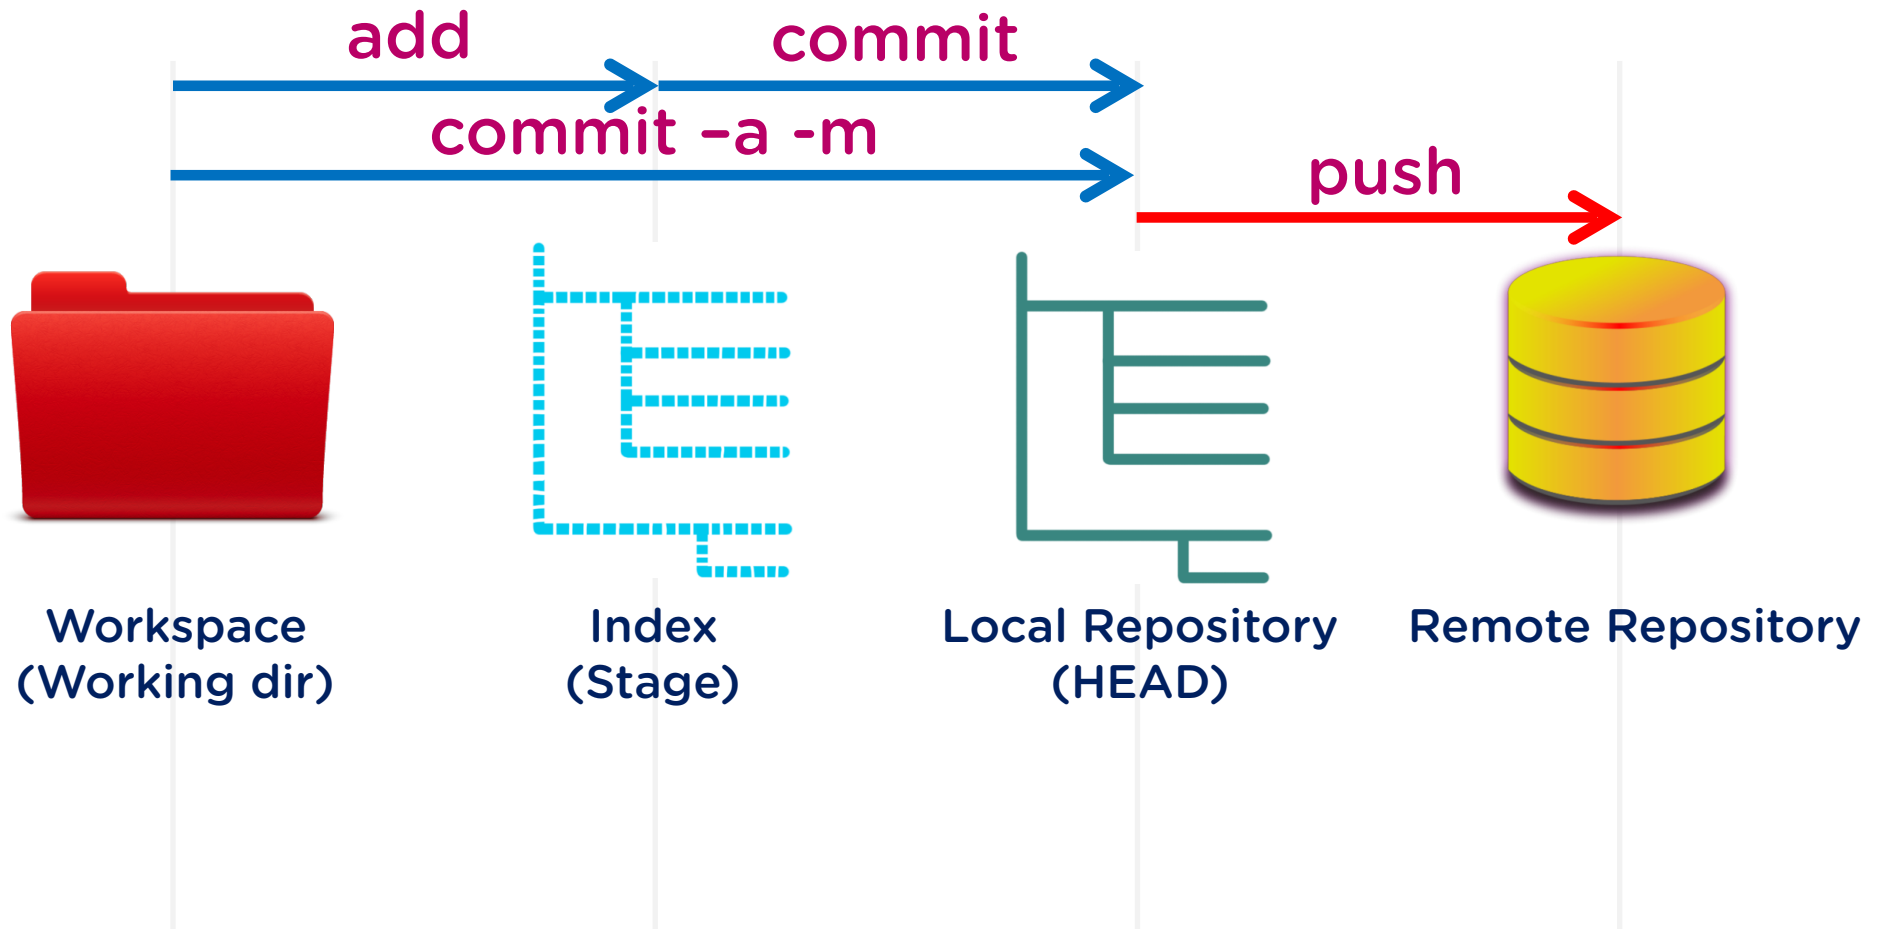

```
$ git remote add origin https://github.com/neuerung/my\_repo.git
```

```
$ git push -u origin master
```

# Git workflow summary

# When things go wrong

# Case 1: My laptop crashed

```
$ cd ~/Documents
```

on your new laptop

```
$ git clone /path/to/repo name/of/new_repo
```

on your new laptop

## Case 2: Forgot to bring my laptop

```
$ cd ~/Documents
```

on your friends laptop

```
$ git clone /path/to/repo name/of/new_repo
```

clone the remote repo to a local repo

```
$ git push origin master
```

once you have completed, push the changes back to remote

```
$ git pull origin master
```

once you are back to your own laptop, pull back the changes to local

# Git workflow summary
